

CTC 96 on graft size. Although the analysis of the experiment was compromised by the inability to use the results of one of the four replicate experiments, the results were clear: CTC 96 regardless of the concentration used, limited the HPV-11-induced growth of the grafts. Even the 0.05% concentration was effective. It is impossible to determine at this stage of the analysis the concentration below which CTC 96 loses its effect on graft size. This question might be answered using other endpoints, histology, capsid protein expression (immunocytochemistry), and viral transcription (RT-PER). This analysis is in progress.

CTC 96 has no effect on the animal's mortality or weight gain. This was expected since the drug was not directly administered to the animals. It was used only to inactivate HPV-11 *in vitro*.
